

Figure 4. Mean fish biomass per size class (\pm standard error). Fish measured by total length (TL) in centimeters (cm).

Spatial sample design

Survey site locations are randomly selected using a depth-stratified design. Logistic and weather conditions factor into the allocation of monitoring effort around each island or atoll. The geographic coordinates of sample sites are then randomly drawn from a map of the area of target habitat (hard-bottom reef) per study area (typically an island or atoll, or in the case of larger islands, sectors per island), within the depth strata of shallow (0-6 m), mid (6-18 m), and deep (18-30 m).

Sampling methods

A pair of divers surveys the fish assemblage at each site using a stationary-point-count method (Fig. 5). Each diver identifies, enumerates, and estimates the total length of fishes within a visually estimated 15-m-diameter cylinder with the diver stationed in the center. These data are used to calculate fish biomass per unit area (g m^{-2}) for each species. Mean biomass estimates per island are calculated by weighting averages by the area per strata. Island-scale estimates presented here represent only the areas surveyed during this cruise.

Each diver also conducts a rapid visual assessment of reef composition, by estimating the percentage cover of encrusting algae, fleshy macroalgae, and hard corals in each cylinder. Divers also estimate the complexity of the reef structure, and take photos along a transect at each site that are archived to allow for future analysis.

Figure 5. Method used to monitor fish assemblage and benthic communities at the Rapid Ecological Assessment (REA) sites.

About the monitoring program

Pacific RAMP forms a key part of the National Coral Reef Monitoring Program of NOAA's Coral Reef Conservation Program (CRCP), providing integrated, consistent, and comparable data across U.S. Pacific islands and atolls. CRCP monitoring efforts have these aims:

- Document the status of reef species of ecological and economic importance
- Track and assess changes in reef communities in response to environmental stressors or human activities
- Evaluate the effectiveness of specific management strategies and identify actions for future and adaptive responses
